PISTON-CYLINDER UNIT

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The invention is concerned with a piston-cylinder unit, having a closed cylinder in which a piston is guided in an axially displaceable manner sealed off from the cylinder via an annular seal radially surrounding it, and divides the cylinder interior into a working space near the piston rod and a working space away from the piston rod, the two working spaces being filled with a fluid, in particular with a hydraulic fluid. A one-sided piston rod extends through the working space near the piston rod and is guided in a sealed manner to the outside through an end closing wall of the cylinder. A first valve can be opened under pressure, in particular under high pressure, to connect the working space away from the piston rod to the working space near the piston rod. A second valve can be opened under high pressure to connect the working space near the piston rod to the working space away from the piston rod. A volume-equalizing chamber receives an amount of hydraulic fluid displaced from the working space away from the piston rod, which is greater than the amount displaced from the working space near the piston rod.

2. Description of the Related Art

[0002] A known piston-cylinder unit of this type has a volume-equalizing chamber which is arranged in an end region of the cylinder and is separated from the working

space away from the piston rod by a partition. This design results in a large overall length and a high outlay on components for the piston-cylinder unit.

[0003] It is therefore the object of the invention to provide a piston-cylinder unit of the type mentioned at the beginning which makes a compact construction with fewer components possible.

SUMMARY OF THE INVENTION

[0004] According to the invention, the volume-equalizing chamber is arranged in the piston, and the working space away from the piston rod can be connected to the volume-equalizing chamber via the first valve, and the working space near the piston rod can be connected to it via the second valve, and in that the volume-equalizing chamber can be connected to the working space away from the piston rod via a first nonreturn valve and can be connected to the working space near the piston rod via a second nonreturn valve.

[0005] Since the cylinder can now be of shortened design and also the piston has at most only to be extended slightly, a very compact piston-cylinder unit is achieved. The integration of the volume-equalizing chamber in the piston furthermore results in a reduction in the components which are required and therefore also in a considerable reduction of costs for the piston-cylinder unit.

[0006] The piston-cylinder unit may be used, for example, as a shock absorber.

[0007] Another advantageous possibility is in the use as a door arrester which acts in an infinitely variable manner, in particular for a door of a motor vehicle.

[0008] So that the volume of the volume-equalizing chamber always corresponds to the volume of fluid which is to be received, it is possible for the volume of the volume-equalizing chamber to be increased under pressure loading and to be reduced under pressure relief.

[0009] One suitable design in this regard involves arranging a volume-equalizing element which reduces its volume under pressure loading and increases its volume under pressure relief in the volume-equalizing chamber.

[0010] In another suitable design of simple construction, the volume-equalizing chamber has a flexible wall designed, in particular, as an elastic diaphragm.

[0011] The first and/or the second valve, which can be opened under high pressure, can be a third and/or fourth force-loaded nonreturn valve, in which case, in a simple design, the first and/or second valve, which can be opened under high pressure, has a closing element which is loaded in the closing direction by a compression spring, in particular by a helical compression spring or a cup-type compression spring.

[0012] One possibility for the first and/or second valve is for the first and/or second valve, which can be opened under high pressure, to be a seat valve.

[0013] In the same manner, the first and/or second valve, which can be opened under high pressure, can advantageously be a slide valve.

[0014] For reliable guidance of the closing elements, the first and/or the second valve, which can be opened under high pressure, can have a valve chamber which is formed in the piston and in which a valve piston is guided displaceably in a sealed manner. The valve piston bears a closing element which is acted upon in the closing direction by a force and is acted upon in the opening direction by the pressure of one of the working spaces, and by means of which the valve passage of the first and/or second valve, which can be opened under high pressure, can be blocked.

[0015] In order, when the piston is at a standstill, to ensure closure of the first and/or second valve, the closing element or the valve piston can be acted upon in the closing direction by a spring.

[0016] This may take place by means of a helical compression spring.

[0017] Another possibility is for the closing element or the valve piston to be acted upon in the closing direction by a force from one or more spring arms which are supported on the piston and the force of which is degressive on the path of movement of the closing element or the valve piston in the opening position, at least in the last part of the path of movement, and is at least largely zero in the opening position. This has the advantage that, during displacement of the piston, the closing element or the valve piston remains in its open position, and, in particular if the piston moves slowly, a fluttering movement of the closing element does not occur.

[0018] Another possibility for acting upon the closing element or the valve piston with force is for the closing element or the valve piston to be acted upon in the closing direction by magnetic forces. In this case too, the closing force drops rapidly and sharply after the closing element is opened.

[0019] This is achieved in a simple manner in that a permanent magnet is arranged on the valve piston or the piston, and a ferromagnetic component is arranged on the piston or valve piston opposite the permanent magnet in the direction of movement of the valve piston.

[0020] In order to reliably retain the closing element in its open position during the displacement process, it is possible for the closing element or the valve piston to be

retained in the opening position of the first and/or second valve with a retaining force which is smaller than the oppositely directed closing force, but added to a pressurization of the valve is larger.

[0021] One advantageously constructed possibility is for the valve piston or the piston to be able to be latched in the opening position with a latching element into a latch on the piston or the valve piston, and for the force for unlatching the latching element from the latch to be the retaining force.

[0022] Finally, it is also possible for a snap spring which is supported with the free end of its snap arm on the piston to be arranged on the piston, the snap arm being in contact with the piston in the axial direction at least largely without any force in the closed position of the valve piston and, in the opening position of the valve piston, acting upon the piston, thus producing the retaining force.

[0023] To reinforce the closing force, on the side facing away from the closing element it is possible for a permanent magnet to be arranged on the valve piston and, facing said permanent magnet, for a further permanent magnet to be arranged on the piston, said permanent magnets butting against each other.

[0024] An integration of functions saving on construction space and components is produced if the annular seal of the piston is designed such that it forms the first and the second nonreturn valve.

[0025] In a simple manner, it is possible for this purpose for the annular seal to have two annular sealing lips at an axial distance from each other, of which the free end regions, which bear against the inner wall of the cylinder, are directed away from each

other, and for the volume-equalizing chamber to be connected to the space between the annular sealing lips via a connecting line, it being possible for the annular sealing lips to be two separate components or else connected to each other in their foot region.

[0026] Another, likewise simple possibility consists in that the annular seal of the piston has a sealing ring which bears elastically against the inner wall of the cylinder and on whose foot region, which is arranged on the piston, valve flaps which extend away axially in opposite directions are integrally formed, said valve flaps being able to be used to close connecting lines which open radially on the piston into the cylinder and lead to the volume-equalizing chamber.

[0027] Other objects and features of the present invention will become apparent from the following detailed description considered in conjunction with the accompanying drawings. It is to be understood, however, that the drawings are designed solely for purposes of illustration and not as a definition of the limits of the invention, for which reference should be made to the appended claims. It should be further understood that the drawings are not necessarily drawn to scale and that, unless otherwise indicated, they are merely intended to conceptually illustrate the structures and procedures described herein.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

[0061] The piston-cylinder units illustrated in the figures are door arresters, which act in an infinitely variable manner, for motor vehicles. They have a closed cylinder 1 in which a piston 2 is guided in a displaceable manner, the piston dividing the interior of the cylinder 1 into a working space 3 near the piston rod and a working space 4 away from the piston rod. The two working spaces 3 and 4 are filled with oil.

[0062] A piston rod 5 is arranged on one side of the piston 2 and extends through the working space 3, and is guided in a sealed manner to the outside through a seal 10 and through an end closing wall 6 of the cylinder 1.

[0063] Arranged adjacent to the closing wall 6 in the working space 3 is an end position damping means 7 comprising a damping piston 8, which can be freely displaced axially in the working space 3, and a compression spring 9, which is arranged between the damping piston 8 and the closing wall 6.

[0064] In order to fasten the piston rod 5 to the piston 2, the latter has a coaxially protruding projection 11 with a coaxial hole 12, into the mouth of which the piston rod 5 is inserted fixedly with its one end.

[0065] Two radial holes 13 open into that region of the coaxial hole 12 which is nearer the piston 2 and to which the piston rod 5 does not reach, and connect the coaxial hole 12 to the working space 3.

[0066] At the piston end, the coaxial hole 12 opens into a valve chamber 14 which is formed in the piston 2 and in which a valve piston 15 is arranged in an axially displaceable manner and sealed by a seal 19 radially surrounding it. The valve piston

15 is provided with a closing element 16 which is the closing element of a seat valve and lies coaxially opposite the mouth of the coaxial hole 12 into the valve chamber 14, which mouth is designed as a valve seat. A helical compression spring 18 which is supported on the bottom 17 of the valve chamber 14 causes the valve piston 15 to act with its closing element 16 against the mouth of the coaxial hole 12, closing it.

[0067] With the exception of the projection 11, that side of the piston 2 which faces the working space 4 is constructed in precisely the same manner as the side which faces the working space 3, and the corresponding components are provided with the reference numbers 12', 14', 15', 16', 17', 18' and 19'.

[0068] Between the two bottoms 17 and 17', a volume-equalizing chamber 20 is formed in the piston 2, the chamber being connected permanently via a first connecting line 21 to the spaces 60 and 60' formed between the valve pistons 15 and 15' and the respective end walls 22 and 22' of the piston 2.

[0069] A volume-equalizing element 23 which reduces its volume under pressure loading and increases it under pressure relief is arranged in the volume-equalizing chamber 20.

[0070] From the first connecting line 21, two connecting lines 24 and 25, which are formed at a distance from each other in the direction of longitudinal extent of the piston 2, lead radially outwards and open on the radially encircling circumferential surface of the piston 2. The mouths of the connecting lines 24 and 25 leading into the gap between the radially encircling circumferential surface of the piston 2 and the inner

wall for the cylinder 1 can be closed by elastic valve flaps 26 and 27 of the first and second nonreturn valves 36 and 37.

[0071] At their mutually facing ends, the valve flaps 26 and 27 are connected integrally to a sealing ring 28 which radially surrounds the piston 2 in the region between the connecting lines 24 and 25. The working spaces 3 and 4 are separated from each other by the sealing ring 28.

[0072] When the piston rod 5 is not subjected to a load, all of the valves are closed and the piston 2 is retained in its position at that particular instance. If a compressive force is exerted on the piston rod 5, the piston 2 moves into the working space 4. The oil pressure produced in the process acts on the closing element 16' and lifts the latter off from its valve seat counter to the force of the helical compression spring 18'. Since the oil pressure now acts on the large surface of the valve piston 15', the latter moves rapidly into its left-hand end position. Furthermore, the oil displaced from the valve chamber 14' is conveyed via the connecting lines 21 and 24 and the opening valve flap 26 into the valve chamber 14, which increases in size. Since the increase in size of the working space 3 on the basis of the volume of the piston rod 5 is smaller than the reduction in size of the working space 4, the excess oil is received by the volume-equalizing chamber 20 with the volume of the volume-equalizing element 23 being reduced.

[0073] At the end of the action of the compressive force on the piston rod 5, all of the chambers again become unpressurized and all of the valves close.

[0074] In the case of an extension movement of the piston rod 5, the same procedure takes place in the reverse direction, oil not only flowing out of the working space 3 via the connecting lines 21 and 25 and the opening valve flap 27, but also the expansion of the volume-equalizing element 23 causing oil to flow out of the volume-equalizing chamber 20 into the working space 4.

[0075] Figures 2 to 15 illustrate the wide variety of arrangements of the lines 21, 24 and 25, arrangements of the nonreturn valves 36 and 37 and arrangements of the volume-equalizing chamber 20 in the piston 2, the function of these parts corresponding to the function in Figure 1.

[0076] Figures 11 to 15 show special refinements of the valve piston 15 and the manner in which it is acted upon by a force. Thus, in Figures 11 and 12, an annular permanent magnet 38 is arranged on the valve piston 15 and a corresponding ferromagnetic component 39 is arranged opposite it on the piston 2. As a result, the piston 15 is retained in its closed position by a high force which drops sharply even after a small movement in the opening direction and thus ensures that the valve is definitely opened. The actual loading for closing purposes takes place by means of the helical compression spring 18.

[0077] In the case of the exemplary embodiment of Figure 12, there is no helical compression spring 18. In this case, the loading for closing purposes also takes place by means of the forces of attraction between the permanent magnet 38 and the ferromagnetic component 39.

[0078] In addition, the loading for closing purposes is also increased by two annular permanent magnets 40, 41. In this case, the permanent magnet 40 is arranged on the valve piston 15, at its end which faces away from the closing element 16, and the further, annular permanent magnet 41 is arranged axially opposite it on the bottom of the valve chamber 14. The repulsion forces of the permanent magnets 40, 41, which are arranged with identical poles facing each other, produce the additional loading for closing purposes.

[0079] In Figure 13, latching hooks 42 are arranged on the valve piston 15 and are prestressed radially inwards by a spring strip 43. In the closed position of the valve piston 15, the latching hook 42 engages with its latching lug 44 in a right-hand latch 45. During opening of the valve, the latching lug 44 is lifted over a bulge 46 and latches in a left-hand latch 47. The unlatching force which is to be overcome in the reverse movement forms a retaining force which is used to retain the valve piston 15 in its open position.

[0080] In Figure 14, a retaining force of this type is exerted by a snap arm 48 of a snap spring 49. The snap spring 49 is fastened to the valve piston 15 and acts with its snap arm 48 upon the piston 2. In the closed position which is illustrated, this action takes place radially and therefore has no effect on an axial displacement of the valve piston 15. If, however, the latter is moved in the opening direction, the snap arm 48 passes into the region of a ramp 50 of the piston 2 and can act with an increasing axial component of force on the valve piston 15 in the opening direction.

[0081] In Figure 15, the valve piston 15 is acted upon in the closing direction by radial spring arms of a disc-type compression spring 51, the force of which is degressive over the path of movement into the open position.

[0082] Figures 16 to 24 show the wide variety of designs of the valve flaps 26 and 27 of the nonreturn valves 36 and 37 and of the sealing ring 28, these three elements being designed as one component with the exception of the embodiment in Figure 16.

[0083] In the exemplary embodiments of Figures 16 and 17, the connecting lines 24 and 25 are combined to form a line which opens into the region between two annular sealing lips 29 and 30, the free end regions of which are directed away from each other. These annular sealing lips 29 and 30 carry out both the function of the valve flaps and also the function of a sealing ring which separates the two working spaces 3 and 4 from each other.

[0084] The sealing ring function is also carried out by the annular sealing lips 31 and 32 in Figures 18 and 23.

[0085] The exemplary embodiments of Figures 18 and 24 additionally have flow by-passes 33 designed as integral components of the sealing ring.

[0086] For easy displaceability, in Figure 22 the elastic sealing ring 28 rests on the inner wall of the cylinder 1 via a sliding ring 34 inserted in a circumferential channel in the sealing ring.

[0087] To fix it in its fitted position, the sealing ring 28 is retained in Figure 23 on the piston 2 by a clamping ring 35 which fits around it.

[0088] Figures 25 to 28 show closing elements 16 of valves which are designed as slide valves, a valve slide 52, which is loaded on the end side by the pressure of the working space 3, being able to move axially in the coaxial hole 12. An axial displacement of the valve slide 52 to the right causes a connection from the working space 3 via a hole 53 to the connecting line 21 (not illustrated) to be opened.

[0089] In order to seal the valve slide 52 in the coaxial hole 12, in Figure 25 the valve slide 52 is provided with an annular seal 54 and in Figure 27 with a sealing cap 55 and in Figures 26 and 28 is produced at its free end completely from an elastomer.

[0090] Exemplary embodiments 29 to 33 show closing elements 16 of seat valves. In this case, in Figure 29 an elastomeric valve ball 56 can be pressed against the valve seat.

[0091] In Figure 30, the valve seat is formed by an elastomer ring 57 surrounding the mouth of the coaxial hole 12.

[0092] Figure 31 corresponds to the embodiment in Figure 1.

[0093] In Figure 32, the closing element 16 is provided on the end side with an elastomer cap 58, and in Figure 33 the closing element 16 bears a sealing ring 59 on its end side.

[0094] Thus, while there have shown and described and pointed out fundamental novel features of the invention as applied to a preferred embodiment thereof, it will be understood that various omissions and substitutions and changes in the form and details of the devices illustrated, and in their operation, may be made by those skilled in the art without departing from the spirit of the invention. For example, it is expressly

intended that all combinations of those elements and/or method steps which perform substantially the same function in substantially the same way to achieve the same results are within the scope of the invention. Moreover, it should be recognized that structures and/or elements and/or method steps shown and/or described in connection with any disclosed form or embodiment of the invention may be incorporated in any other disclosed or described or suggested form or embodiment as a general matter of design choice. It is the intention, therefore, to be limited only as indicated by the scope of the claims appended hereto.
